Conclusion

# Lightweight crypto ?

We expect RFID tags to be deployed widely (supply chain management, e-passports, contactless applications, etc.)

- we need to ensure authentication and/or confidentiality
- a basic RFID tag may have a total gate count of anywhere from 1000-10000 gates, with **only 200-2000 gates** budgeted for security
- hardware throughput and software performances are not the most important criterias, but they must be acceptable
- in general aim for smallest possible area, good FOM (throughput/area<sup>2</sup>), acceptable speed (hardware and software)
- block ciphers and hash functions are used as basic blocks for RFID device authentication and privacy-preserving protocols.

▲ロト ▲ □ ト ▲ □ ト ▲ □ ト ● ● の Q ()

# Lightweight hash functions ?

# Standardized or SHA-3 hash functions are too big:

- MD5 (8001 GE), SHA-1 (6122 GE), SHA-2 (10868 GE)
- BLAKE (9890 GE), GRØSTL (14622 GE), JH (?), KECCAK (20790 GE), SKEIN (12890 GE)

# Recently, new lightweight hash functions have been proposed (much lower than 10000 GE):

- MAME [Yoshida et al. 2007]
- DM-PRESENT and H-PRESENT [Bogdanov et al. 2008]
- ARMADILLO [Badel et al. 2010]
- QUARK [Aumasson et al. 2010]
- PHOTON [Guo et al. 2011]
- SPONGENT [Bogdanov et al. 2011]

# Lightweight block ciphers ?

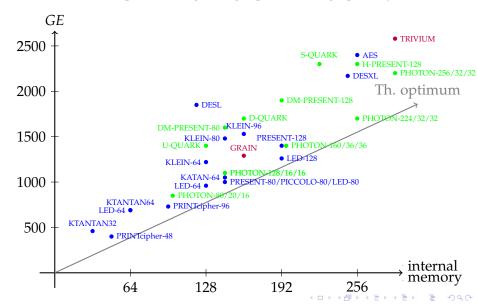

More mature than hash functions, but are lightweight block ciphers too provocative ?

- ARMADILLO: key-recovery attacks [A+-2011]
- HIGHT: related-key attacks [K+-2010]
- Hummingbird-1: practical related-IV attacks [S-2011]
- KTANTAN: practical related-key attacks [Å-2011]
- PRINTcipher: large weak-keys classes [ÅJ-2011]

 $\ensuremath{\texttt{PRESENT}}$  and  $\ensuremath{\texttt{LED}}$  are still unbroken.

# Lightweight $\simeq$ low memory

The storage of one bit depends the technology, but for UMC 180nm it costs about:

- 4.67 GE for one input flip-flop
- 6 GE for two inputs flip-flop

Of course, all the security parameters will be small in order to avoid any waste of memory because of unwanted extra security:

- block ciphers: 64-bit block, 64 to 128-bit key
- hash functions: depends on security property. Can go from 64-bit hash output for preimage up to 256-bit output for collision resistance

Minimizing the memory for block ciphers

Minimizing the memory for block ciphers:

- Key schedule:
  - avoid complex key expansion or non-invertible key schedules !
  - use simple invertible key register update (AES, PRESENT, KATAN)
  - or subkeys simply selected from master key bits (IDEA, PICCOLO, KTANTAN)
  - or no key schedule: subkeys = master key (LED)
  - for the two last, one can hardwire the key and further save memory in some scenarios

# Internal permutation:

- use general construction that allows maximal serialisation
- avoid classical Feistel, better to use Feistel with many branches (for a light internal function *F*, one can use the PICCOLO trick)
- for SPN, use small MixColumns (or use PHOTON/LED trick)

# Orginial sponge functions [Bertoni et al. 2007]

A sponge function has been proven to be indifferentiable from a random oracle up to  $2^{c/2}$  calls to the internal permutation *P*. However, **the best known generic attacks have the following complexity:** 

- **Collision:**  $\min\{2^{n/2}, 2^{c/2}\}$
- Second-preimage: min{2<sup>n</sup>, 2<sup>c/2</sup>}
- Preimage:  $\min\{2^{\min\{n,c+r\}}, \max\{2^{\min\{n-r,c\}}, 2^{c/2}\}\}$

Minimizing crypto

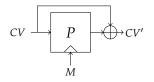

PHOTON

Conclusion

## Sponges vs Davies-Meyer

We would like to build the smallest possible hash function with no better collision attack than generic ( $2^{n/2}$  operations). Thus we try to minimize the internal state size:

 in a classical Davies-Meyer compression function using a *m*-bit block cipher with *k*-bit key, one needs to store 2*m* + *k* bits. We minimize the internal state size with *m* ≃ *n* and *k* as small as possible.

• **in sponge functions**, one needs to store *c* + *r* bits. We minimize the internal state size by using *c* ≃ *n* and a bitrate *r* as small as possible.

# Sponge function will require about twice less memory bits for lightweight scenarios.

Minimizing crypto

PHOTON

Conclusior

# Basic lightweight design tricks

• **constants:** use no constants, or at least some that are easy to generate with a LFSR (avoid pure counter)

# • non-linearity:

- use NLFSR (KATAN)
- use NAND gates (KECCAK)
- use small Sboxes (PRESENT, LED, PICCOLO...). 4-bit Sboxes seem a good compromise between size (PRESENT Sbox is about 20GE) and cryptographic quality, since a 8-bit Sbox is quite big (AES Sbox is about 230 GE)

# • diffusion:

- use bit position permutation branching (PRESENT): almost no diffusion (the diffusion is provided by the Sboxes), but fast and lightweight ... be carefull with hull effect
- serially computable MDS (PHOTON, LED): very good diffusion, lightweight, but slow

# MDS Matrix

What is an **MDS Matrix** ("Maximum Distance Separable")?

- it is used as **diffusion layer** in many block ciphers and in particular AES
- it has excellent diffusion properties. In short, for a *d*-cell vector, we are ensured that at least d + 1 input / output cells will be active ...
- ... which is very good for linear / differential cryptanalysis resistance

The AES diffusion matrix can be implemented fast in software (using tables), but the situation is not so great in hardware. Indeed, even if the coefficients of the matrix minimize the hardware footprint, d - 1 cells of temporary memory are needed for the computation.

$$A = \begin{pmatrix} 2 & 3 & 1 & 1 \\ 1 & 2 & 3 & 1 \\ 1 & 1 & 2 & 3 \\ 3 & 1 & 1 & 2 \end{pmatrix}$$

Tweaking AES for hardware: AES-HW

The smallest AES implementation requires 2400 GE with 263 GE dedicated to the MixColumns layer (the matrix *A* is MDS).

	( 2	3	1	1		( 1	4	11	13	9)
4 _	1	2	3	1	∧ <sup>-1</sup> _	9	)	14	11	13
Λ —	1	1	2	3	л —	1	3	9	14	11
A =	3	1	1	2 )	$A^{-1} =$	$\backslash 1$	1	13	9	14 /

A tweaked AES-HW implementation requires 2210 GE with 74 GE dedicated to the MixColumnsSerial layer (the matrix  $(B)^4$  is MDS):

$$(B)^{4} = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 2 & 1 & 4 \end{pmatrix}^{4} = \begin{pmatrix} 1 & 2 & 1 & 4 \\ 4 & 9 & 6 & 17 \\ 17 & 38 & 24 & 66 \\ 66 & 149 & 100 & 11 \end{pmatrix} \qquad B^{-1} = \begin{pmatrix} 2 & 1 & 4 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{pmatrix}$$

### Domain extension algorithm

The (c + r)-bit internal state is viewed as a  $d \times d$  matrix of *s*-bit cells.

PHOTON- <i>n/r/r</i>		n	С	r	r'	d	S
PHOTON-80/20/16	P <sub>100</sub>	80	80	20	16	5	4
PHOTON-128/16/16	P <sub>144</sub>	128	128	16	16	6	4
PHOTON-160/36/36	P <sub>196</sub>	160	160	36	36	7	4
PHOTON-224/32/32	P <sub>256</sub>	224	224	32	32	8	4
PHOTON-256/32/32	P <sub>288</sub>	256	256	32	32	6	8
				<ul> <li>Image: Image: Ima</li></ul>	• • 🗗 • ·	< ≣ > -	< ≣ >

200

The internal permutations apply **12 rounds** of an AES-like fixed-key permutation:

s bits

d cells

- AddConstants: xor round-dependant constants to the first column
- **SubCells:** apply the PRESENT (when *s* = 4) or AES Sbox (when *s* = 8) to each cell
- ShiftRows: rotate the i-th line by i positions to the left
- MixColumnsSerial: apply the special MDS matrix to each columns

AES-like fixed-key permutation security

- AES-like permutations are simple to understand, well studied, provide very good security
- one can easily derive clear and powerful proofs on the minimal number of active Sboxes for 4 rounds of the permutation:  $(d + 1)^2$  active Sboxes for 4 rounds of PHOTON
- **we avoid any key schedule issue** since the permutations are fixed-key

	P <sub>100</sub>	P <sub>144</sub>	P <sub>196</sub>	P <sub>256</sub>	P <sub>288</sub>
differential path probability	$2^{-72}$	$2^{-98}$	$2^{-128}$	$2^{-162}$	$2^{-294}$
differential probability	$2^{-50}$	$2^{-72}$	$2^{-98}$	$2^{-128}$	$2^{-246}$
linear approximation probability	2 <sup>-72</sup>	$2^{-98}$	$2^{-128}$	$2^{-162}$	$2^{-294}$
linear hull probability	$2^{-50}$	$2^{-72}$	$2^{-98}$	$2^{-128}$	$2^{-246}$

 Table: Upper bounds for 4 rounds of the five PHOTON internal permutations.

Introduction	Minimizing memory	Minimizing crypto	PHOTON	LED	Conclusion
	00 000				

### Rebound attack and improvements

The currently best known technique achieves **8 rounds** for an AES-like permutation, with quite low complexity.

	P <sub>100</sub>	$P_{144}$	P <sub>196</sub>	P <sub>256</sub>	P <sub>288</sub>
computations	28	2 <sup>8</sup>	2 <sup>8</sup>	2 <sup>8</sup>	2 <sup>16</sup>
memory	24	2 <sup>4</sup>	2 <sup>4</sup>	2 <sup>4</sup>	2 <sup>8</sup>
generic	2 <sup>10</sup>	2 <sup>12</sup>	2 <sup>14</sup>	2 <sup>16</sup>	2 <sup>24</sup>

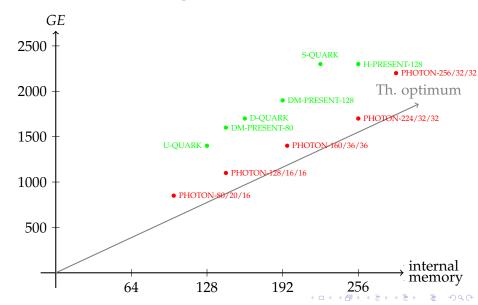

Improvements are unlikely since no key is used in the permutation, so the amount of freedom degrees given to the attacker is limited to the minimum.

# Other cryptanalysis techniques

- **cube testers:** the best we could find within practical time complexity is at most 3 rounds for all PHOTON variants.
- **zero-sum partitions:** distinguishers for at most 8 rounds (for complexity  $< 2^{c/2}$ ).
- algebraic attacks: the entire system for the internal permutations of PHOTON consists of *d*<sup>2</sup> · *N<sub>r</sub>* · {21, 40} quadratic equations in *d*<sup>2</sup> · *N<sub>r</sub>* · {8, 16} variables.
- **slide attacks on permutation level:** all rounds of the internal permutation are made different thanks to the round-dependent constants addition.
- slide attacks on operating mode level: the sponge padding rule from PHOTON forces the last message block to be different from zero.
- **rotational cryptanalysis:** any rotation property in a cell will be directly removed by the application of the Sbox layer.
- **integral attacks:** can reach 7 rounds with complexity  $2^{s(2d-1)}$ .

### A single round of LED

The 64-bit round function is an SP-network (we apply **32** to **48 rounds**):

- AddConstants: xor round-dependent constants to the two first columns
- **SubCells:** apply the PRESENT 4-bit Sbox to each cell
- ShiftRows: rotate the i-th line by i positions to the left
- **MixColumnsSerial:** apply the special MDS matrix to each columns independently

イロト 不得 とくほ とくほとう

#### Conclusion

### Example: LED key schedule

For **64-bit key**, the key is xored to the internal state **every four rounds**. In related-key setting, one gets at least half of the boxes active:

For **up to 128-bit key**, the key is divided into **two equal chunks**  $K_1$  and  $K_2$  that are alternatively xored to the internal state **every four rounds**. In related-key setting, one gets at least half of the boxes active:

LED

#### Differential/linear attacks

- AES-like permutations are simple to understand, well studied, provide very good security
- In single-key model: one can easily derive proofs on the minimal number of active Sboxes for 4 rounds of the permutation:

 $(d+1)^2 = 25$  active Sboxes for 4 rounds of LED

• In related-key model: we have at least half of the 4-round steps active, using the same reasoning we obtain:  $(d+1)^2 = 25$  active Sboxes for 8 rounds of LED

	LED-64 SK	led-64 RK	LED-128 SK	LED-128 RK
minimal no. of active Sboxes	200	100	300	150
differential path probability	2-400	$2^{-200}$	$2^{-600}$	$2^{-300}$
linear approx. probability	2-400	$2^{-200}$	$2^{-600}$	$2^{-300}$

In the **chosen-related-key model**, one can distinguish **15** rounds (over 32) of LED-64 with complexity  $2^{16}$ 

In the **chosen-related-key model**, one can distinguish **27 rounds** (over 48) of LED-128 with complexity  $2^{16}$ 

Improvements are unlikely since no key is used during four rounds of the permutation, so the amount of freedom degrees given to the attacker is limited to the minimum.

Conclusion and Future Works

## Conclusion

PHOTON and LED:

- are very simple, clean and based on the AES design strategy
- are one of the **smallest hash functions/block ciphers** (both use serially computable MDS)
- have acceptable software performances
- provide **provable security** against classical linear/differential cryptanalysis **both in the single-key and related-key models for** LED
- have a large security margin:
  - PHOTON: very small amount of freedom degrees given to the attacker per iteration
  - LED: security analysis done in the very optimistic known/chosen-keys model, margin especially large in the single-key model.

### Future Works

- cryptanalysis !
- **other aims** than minimal area are possible: high throughput, energy consumption, a little bit everything, ...
- better **key schedule**: can we find key schedules that provably closes the gap between single-key and related-key models ?
- better **MDS matrices**: can we find matrices that offer good diffusion (maybe not MDS), with hardware-friendly serial decomposition (maybe not fully serial), and with less clock cycles ... find the best tradeoff.
