## **Block Cipher**

#### Definition

A block cipher  $E : \{0,1\}^k \times \{0,1\}^n \rightarrow \{0,1\}^n$  is a family of efficiently invertible permutations on *n*-bit values, whose index is a *k*-bit key value.

#### Applications in Cryptography: a fundamental primitive

- ► Encryption Scheme: ECB, CBC, CFB, OFB, CTR
- Message Authentication Code: EMAC, CMAC, PMAC
- Authenticated Encryption: GCM, OCB, EAX, CCM
- ► Hash Function: PGV schemes, MDC-2, MJH, Hirose Scheme

Application to PRESENT

Conclusion 00

# Security Requirement on Block Cipher

A classical security notion: the indistinguishability from an ideal block cipher.

#### Ideal Block Cipher

Each permutation indexed by a key value is a random permutation. Moreover, any two permutations indexed by distinct key values are completely independent.

# Attack Models on Block Cipher

#### Secret-key Model

- Secret key value
- Impact to Encryption, MAC
- Single-key attack
- Related-key attack

#### **Open-Key Model**

- Public key value
- Impact to Hash Function
- Known-key attack
- Chosen-key attack

New Distinguisher

Application to PRESENT

Conclusion 00

### Attack Models on Block Cipher

- Open-key model is more generous to adversary.
- More rounds are expected to be attacked in open-key model.
- For AES-128 as an example, the number of attacked rounds is Secret-key model: 7 rounds [DFJ13];
   Open-key model: 10 (full) rounds [Gilbert14].

Conclusion 00

### Attack Models on Block Cipher

- Open-key model is more generous to adversary.
- More rounds are expected to be attacked in open-key model.
- For AES-128 as an example, the number of attacked rounds is Secret-key model: 7 rounds [DFJ13];
   Open-key model: 10 (full) rounds [Gilbert14].

Interestingly the situation for standardized lightweight block cipher **PRESENT** is rather different, which motivates this research.

New Distinguisher

Application to PRESENT

Conclusion 00

### PRESENT Cipher

- ISO/IEC standard lightweight block cipher
- Block size is 64 bits; Key size is 80 bits (referred to as PRESENT-80) or 128 bits (referred to as PRESENT-128).
- Composed of 31 rounds:

Each round consists of a round-key XOR, an Sbox layer and a simple linear bit permutation layer

Figure: One round of PRESENT

Conclusion 00

### Previous Analysis Results on PRESENT

- Most scrutinized lightweight cipher.
- Multidimensional linear attack is the most powerful one: easy-to-trace linear trails with large correlations
- Link between differential property and linear correlation in [BN14]:

A multidimensional linear distinguisher can be converted to a truncated differential distinguisher.

New Distinguisher

Application to PRESENT

Conclusion 00

## Known-Key Distinguisher

- Key is known to the distinguisher
- Improve estimation of the security margin of block cipher
- Encompass the scenario of block cipher-based hash function
- The goal for an attacker:

generate input/output pairs with a certain property, such that the complexity for the target block cipher is lower than the generic complexity when dealing with an ideal block cipher

 target block cipher: open access to internal states to exploit structural weakness;

- ideal block cipher: black-box access to encryption and decryption oracles  $% \left( {\left| {{{\mathbf{x}}_{i}} \right|} \right)$

Conclusion 00

# Our Known-Key Distinguisher

### Distinguishing property

Find a set of N plaintexts, such that they all have the same value on s pre-determined bits and such that there is a bias on the number of collisions observed on q pre-determined bits of corresponding ciphertexts

Generic attack on an ideal block cipher:

- Pick N random plaintexts having the same values on s pre-determined bit positions
- Query them, and count the number of collisions on the *q* pre-determined bit positions of corresponding ciphertexts

Application to PRESENT

Conclusion 00

### Application to PRESENT

It is important to study known-key distinguishers on PRESENT.

- a natural candidate to build a lightweight hash function
- DM-PRESENT and H-PRESENT in [BL+08]

We decided to base our distinguisher on truncated differential attacks, because

- it can reach the maximum number of attacked rounds
- it is easier to handle than multidimensional linear attack in the known-key setting

Conclusion 00

## Application to PRESENT

It is important to study known-key distinguishers on PRESENT.

- a natural candidate to build a lightweight hash function
- DM-PRESENT and H-PRESENT in [BL+08]

We decided to base our distinguisher on truncated differential attacks, because

- it can reach the maximum number of attacked rounds
- it is easier to handle than multidimensional linear attack in the known-key setting

On the other hand,

- its statistical bias is small, and a large number of plaintexts is necessary
- pre- and post-adding extra differential characteristics cannot work well, since they reduce #available plaintexts.

## Truncated Differential Layer

- [BN14] studies the link between the probability of a truncated differential and the capacity of a multidimensional linear approximation.
- Truncated differential with strong bias on PRESENT: both plaintext and ciphertext have only one Sbox with no difference.
- The truncated differential in our attack:
  - Plaintext:  $S_{13}$  has no difference
  - Ciphertext: one of  $S_5$ ,  $S_7$ ,  $S_{13}$  or  $S_{15}$  has no difference
- Such a truncated differential on 24-round PRESENT:
  - its probability is  $2^{-4} + 2^{-62.77}$
  - for an ideal block cipher, the probability is  $2^{-4}$

Known-Key Distinguisher on Full PRESENT

C. Blondeau, T. Peyrin, L.Wang

New Distinguisher

Application to PRESENT

Conclusion 00

## Meet-in-the-Middle Layer

It sets constraints only on its input and output, which maintains as many as possible valid inputs to truncated differential layer

- input bit constraints: define the distinguishing property.
- output bit constraints: consistent with truncated differential.

Known-Key Distinguisher on Full PRESENT

C. Blondeau, T. Peyrin, L.Wang

イロト 不得 とうせい かほとう ほ

New Distinguisher

Application to PRESENT

Conclusion 00

## Meet-in-the-Middle Layer

Identify all valid plaintexts efficiently:

• meet-in-the-middle approach due to small Sbox and bit-permutation linear layer:

in two rounds, an input bit interacts with few other bits, and impacts to only partial outputs bits

Known-Key Distinguisher on Full PRESENT

C. Blondeau, T. Peyrin, L.Wang

New Distinguisher

Application to PRESENT

Conclusion 00

## Meet-in-the-Middle Layer

Attack procedure on 7-round PRESENT:

- 1. Guess and forward compute the first two rounds
- 2. Guess and backward compute the last one round and half
- 3. Gradually match the two independent computations through the middle three rounds

Known-Key Distinguisher on Full PRESENT

C. Blondeau, T. Peyrin, L.Wang

.⊒ . ►

New Distinguisher

Application to PRESENT

Conclusion 00

## Meet-in-the-Middle Layer

Gradually match through the middle three rounds

- divide into 4-Sbox groups
- forward: [S<sub>4i</sub>, S<sub>4i+1</sub>, S<sub>4i+2</sub>, S<sub>4i+3</sub>] as group TF<sub>i</sub> group TF<sub>0</sub> as an example: red color
- backward: [S<sub>4i</sub>, S<sub>4i+4</sub>, S<sub>4i+8</sub>, S<sub>4i+12</sub>] as group TB<sub>i</sub> group TB<sub>0</sub> as an example: blue color

Known-Key Distinguisher on Full PRESENT

C. Blondeau, T. Peyrin, L.Wang

New Distinguisher

Application to PRESENT

Conclusion 00

### Meet-in-the-Middle Layer

The procedure of gradually matching:

- 1. guess and compute each group independently
- 2. merge  $TF_i$  and  $TB_i$ , and store the results in table  $T_i$
- 3. merge  $T_0$  and  $T_1$ ,  $T_2$  and  $T_3$ , independently, and store the results in  $T_{0,1}$  and  $T_{2,3}$  respectively
- 4. merge  $T_{0,1}$  and  $T_{2,3}$
